

The Operating System

A plain-language overview — what we're building, where we are, how it works, and what it's worth.

Prepared July 27, 2026.

What we're trying to accomplish

We're building an **AI-powered operating system for the companies** — one place that watches the business, tells you what needs a decision, and does the repetitive work itself, with a person approving anything that leaves the building.

The goal is simple: **stop paying people to do busywork**. Start with the work that's pure repetition and pure dollars — **chasing overdue invoices** — and let the system draft every reminder, track every promise, and make sure no invoice ever quietly ages. Then expand from there.

Think of it as a tireless assistant who never forgets, never drops a follow-up, and never sends anything to a customer without you saying "yes" first.

Where we are today

It is **built and running live**, on our own secure server, behind a company login. Two pieces already work on **real company data**:

- **Sales watch** — it reads our Pipedrive deals and flags the ones going stale or past their expected close date, so deals stop slipping through the cracks. This is **live right now**.
- **Collections** — it reads our **real accounts receivable straight out of Acumatica** (our accounting system), sees exactly who owes what and how overdue they are, and **writes the chase email for each one**. The AR person opens a prioritized list where every message is already drafted — their job is to read it, adjust if needed, and approve. Built and tested against our live books; activation is a documented, staged checklist.

When we first pointed it at our real receivables it saw **roughly \$340,000 past due across FS and Big League**. One caveat we found and fixed: that first look counted invoices but not the credits sitting on customer accounts, so the true net is **lower** than \$340K — we'll have the real number on the first live run. Better to say that now than to chase a customer for money they've already been credited.

How it works (the simple version)

1. **It reads the truth from our real systems.** Money comes from Acumatica, deals from Pipedrive. It never guesses or makes numbers up — it reads the actual records.
2. **It turns "things that need doing" into a clear to-do list** in one screen (we call it the tower): which customer to chase, which deal is stalling, what needs your decision.
3. **It drafts the actual work** — the reminder email, the follow-up, the packet — so a person's whole job is *reading and clicking yes or no*.
4. **Nothing goes out without a human.** It never sends an email or takes an outside action on its own. It prepares; you approve.
5. **It records everything** it does, permanently, so there's a clean trail.

The one rule that makes it safe: **it drafts, you approve.** A person is always the final "send" button.

What it can read from Acumatica — today, and next

The important thing to understand is what the **connection to Acumatica** is. Acumatica is where the real numbers live, and we've built a secure, read-only pipe into it. That pipe is the capability. What we point it at grows over time — same pipe, more of the picture:

- **Today — the money we're owed.** Right now it reads **accounts receivable** (who owes us, how much, how overdue — netted against their credits) plus the **customer contact** to address a chase to. That is all it reads so far.
- **Next — actual sales.** The *same connection* reaches our real **sales and revenue** — what's actually been sold and invoiced, by company, not a salesperson's guess in the CRM. This is built to be turned on next; it isn't reading yet.
- **After that — the full scoreboard.** From the same pipe: open orders, margin, how long it takes us to collect. The live "how's the business doing" numbers, straight from the books instead of a hand-built spreadsheet.

A note on the CRM (Pipedrive): it is **only a status board for deals in progress** — it tells us which deals are stalling. It is **not** where the real sales numbers come from. **The truth is Acumatica; the CRM is just a nudge list.** So when this doc says "reads the truth," today that means the receivables; the sales and scoreboard numbers are the same capability, switched on in turn.

What it changes

*One hard number so far, and it's not a savings estimate — it's what the system saw when it read the real books: **on the order of \$340K of receivables past due across FS and Big League,***

pending the credit netting described above. That's current exposure, measured, not a projection. What the system does with it:

- **Every overdue invoice gets worked systematically.** Each one goes on a chase ladder — a friendly nudge, then firmer, then a call task — instead of getting chased whenever someone gets to it. Whether that pulls cash in faster is something we'll measure once it's running, not something we're claiming up front.
- **The manual hunting goes away.** Today the AR person digs through the aging report and writes each email from scratch. The system hands them a prioritized list with the draft already written — they review and click. We haven't put an hours number on that; the point is the busywork moves off the person.
- **Nothing falls through.** Every overdue account and every stalling deal is surfaced automatically — no "we forgot to follow up on that one."
- **One version of the truth.** The numbers come straight from Acumatica, replacing the manual exporting and re-typing we do today.
- **Build once, reuse everywhere.** The same engine that runs collections will run the scoreboard, other departments, and the other companies. Each new use is an add-on, not a rebuild.

What's next

- **Switch collections on.** The work is done and tested; what remains is a staged checklist against the live system — confirm the numbers reconcile with Acumatica's own aging report, look at real drafted chases, then let the morning refresh run itself.
- **Put the draft in the mailbox.** Today the system writes the chase and the AR person approves it; the last hop is depositing that text directly into the AR mailbox as a Gmail draft. Deliberately a separate decision, because it's the step that touches an outside system.
- **Light up the scoreboard** — pull revenue, margin, days-to-collect, and orders straight from Acumatica so the numbers are live, not hand-built.
- **Add a chat** you can just ask: *"What's our exposure with customer X?" "What needs my decision today?"*

The bottom line

We've gone from an idea to a **live, secure system that reads our real money and deals**, with the safety rail that a human approves everything. The collections loop is now built end to end: it reads the books each morning, decides who to chase and how firmly, and **writes each**

email so the AR person reviews instead of types. What's left is switching it on against the live system and checking the numbers reconcile — not more building.
